# Section I — Identity and lifecycle

## 1.1 — Identity

| Di-<br>rec-<br>tive   | Form                                                                              | Notes                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------|-----------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| hea-<br>der /<br>id   | <code>@@@tem-<br/>plate<br/>&lt;id&gt; [in-<br/>herits<br/>&lt;parent&gt;]</code> | Opens the entity, MUST come first. <code>id</code> : no spaces, a Unicode letter then Unicode letters/digits/ <code>_</code> . <b>CASE- AND DIACRITIC-INSENSITIVE</b> , canonical form UPPERCASE ( <code>Explain / explain / EXPLAIN</code> — and <code>café / Café / CAFE</code> — name the SAME entity ; a redefinition is <code>DUPLICATE_DECLARATION</code> ). Used by includes, inheritance, collections. MAY be qualified <code>&lt;collection&gt;{.&lt;sub-collection&gt;}.&lt;id&gt;</code> — containment depth is UNBOUNDED (collections nest). |
| name                  | <code>@@@name<br/>&lt;text&gt;</code>                                             | Human-readable. Spaces allowed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| des-<br>crip-<br>tion | <code>@@@des-<br/>cription<br/>&lt;text&gt;</code>                                | Short prose. Spaces allowed. OPTIONAL.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

`@@@template` and `@@@name` are MANDATORY for a structured (L1+) prompt; `@@@description` is OPTIONAL — its omission renders normally and only raises the advisory `MISSING_DESCRIPTION` warning. There is no separate `@@@id` directive: the `id` rides on the `@@@template` header.

## 1.2 — Lifecycle markers

| Directive  | Form                                                       | Purpose                                                                       |
|------------|------------------------------------------------------------|-------------------------------------------------------------------------------|
| alias      | <code>@@@alias &lt;old_id&gt;</code>                       | Old id keeps resolving to the canonical id. Multiple allowed.                 |
| deprecated | <code>@@@deprecated<br/>"&lt;migration message&gt;"</code> | Informational ; triggers DEPRECATED_TEMPLATE warning. At most one per prompt. |

## 1.3 — Template-level OO<sup>2</sup> markers (L5)

| Modifier | Form                                                         | Purpose                                                                  |
|----------|--------------------------------------------------------------|--------------------------------------------------------------------------|
| virtual  | <code>@@@template virtual<br/>&lt;coll&gt;.&lt;id&gt;</code> | Abstract : a derived collection<br>MUST override this prompt by id.      |
| final    | <code>@@@template final<br/>&lt;coll&gt;.&lt;id&gt;</code>   | Sealed : a derived collection<br>MUST NOT override this prompt<br>by id. |

`virtual` and `final` are MODIFIERS on the `@@@template` header, written immediately after the keyword — never standalone directives (a bare `@@@virtual` / `@@@final` is `INVALID_SYNTAX`). They are mutually exclusive (combining them is `INVALID_SYNTAX`).

## 1.4 — Recommended writing order

Identity → Lifecycle (alias, deprecated) → Parameters → Constants → [Content] → Attachments. Processors MUST accept any order ; this is just for readability.

## Skills and local drafts

`@@@template + @@@type skill / @@@template-body / @@@end-template`: prompt composition aliases. The requested declaration owns the type. `allow` warns on mixed inheritance; `deny` rejects reached mixed edges, including collection-member overrides. Includes `keep` the consumer's type. Search `type:skill` and `flag:draft`. Local draft saves `keep` the UUID and stay outside shared versions/Git. Publish is explicit, checks conflicts and published dependencies, and never promotes other drafts automatically. Export SKILL.md/ZIP; installed copies update manually.

## Templates and document nature

A **template** is the common reusable entity. Its **Nature** is `prompt`, `skill` or a custom identifier such as `mod` or `acme.review`. Create **New prompt** or **New skill**, then edit Nature in Properties when needed. Changing nature preserves the UUID, references, parameters and history. The leaf template owns its type; includes never change it. Mixed inheritance can be allowed with warnings or denied.

```
@@@template review_assistant
@@@type skill
@@@description Reusable review instructions
@@@section rules
Separate observations from assumptions.
```

Use `type:acme.review` to search a custom nature. The **Example** flag replaces the old Template flag; `flag:example` finds these starting examples. `flag:draft` continues to find private drafts. A prompt copies the rendered text, a skill exports SKILL.md and resources, and other types export composed text without claiming a specialized package format.

## Section II — Sections

A section declaration combines three independent axes — all optional, freely combinable (with one exception: `virtual` and `final` cannot coexist).

```
@@@section[?|!] [virtual|final] <name>[.<child>] [first|last|before <anchor>]
```

### 2.1 — The three axes

| Axis                         | Values                                                 | Effect                                                                                                                                                                               |
|------------------------------|--------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Pre-<br>sence<br>toggle      | rien / ? / !                                           | rien = always rendered ; ? = user dialog, default OFF ; ! = user dialog, default ON                                                                                                  |
| Inheri-<br>tance<br>modifier | rien / virtual / final / delete                        | rien = ordinary ; virtual = abstract (descendant must implement) ; final = sealed (descendants must not redeclare) ; delete = an INHERITED section renders nothing, heading included |
| Trans-<br>parency            | rien / (<name>)                                        | Parentheses around the NAME, at the declaration only : the section emits no heading of its own, and what it governs follows                                                          |
| Place-<br>ment               | rien / first / last / before <anchor> / after <anchor> | Positions a section an INHERITING prompt ADDS, relative to the inherited skeleton. Default = appended after the inherited sections.                                                  |

There is NO numbering axis ( [`<N>`] ): list items are dotted **sub-sections** `<parent>.<child>` ( `@@@section steps.one` ), declared AND accessed in dotted form — never `steps[1]` .

`?` and `!` glue directly to the `section` keyword ( `@@@section?` ), never to the name. The `virtual` / `final` modifier follows the toggle, before the name — it is never a directive of its own (a bare `@@@virtual` / `@@@final` is `INVALID_SYNTAX` ). The placement clause is valid ONLY on a section an inheriting prompt `ADDS` ( `INVALID_SECTION_PLACEMENT` otherwise); `<anchor>` MUST be an inherited section ( `INVALID_SECTION_ANCHOR` ).

## 2.2 — Description rules

- **Mandatory** when the toggle is `?` or `!` (it's the dialog text) — `TOGGLEABLE_SECTION_WITHOUT_DESCRIPTION` otherwise; an empty `:` counts as absent.
- **Never rendered.** The heading is the section's NAME; a description is dialog prose, or a note for the author on a plain section.
- Introduced by a colon: `: <description>` .
- Not quoted — contrast with `param` / `const` labels which use `"<label>"` .

## 2.3 — All forms at a glance

| Form                                       | Meaning                               |
|--------------------------------------------|---------------------------------------|
| <code>@@@section foo</code>                | Always rendered, no dialog            |
| <code>@@@section<br/>foo.one</code>        | Sub-section (dotted), always rendered |
| <code>@@@section<br/>foo.one : desc</code> | Sub-section, with description         |

| Form                                                | Meaning                                                                                                                                               |
|-----------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>@@@section?</code><br><code>foo : desc</code> | User dialog, default OFF                                                                                                                              |
| <code>@@@section!</code><br><code>foo : desc</code> | User dialog, default ON                                                                                                                               |
| <code>@@@section virtual foo</code>                 | Abstract, descendant must implement                                                                                                                   |
| <code>@@@section? virtual foo : desc</code>         | Abstract + dialog default OFF                                                                                                                         |
| <code>@@@section! virtual foo : desc</code>         | Abstract + dialog default ON                                                                                                                          |
| <code>@@@section final foo</code>                   | Sealed, no override allowed                                                                                                                           |
| <code>@@@section? final foo : desc</code>           | Sealed + dialog default OFF                                                                                                                           |
| <code>@@@section! final foo : desc</code>           | Sealed + dialog default ON                                                                                                                            |
| <code>@@@section bar last</code>                    | Added section, placed after inherited ones                                                                                                            |
| <code>@@@section (bloc)</code>                      | Transparent: no heading of its own; its sub-sections emit their RANK alone ( <code>1.</code> , <code>2.</code> )                                      |
| <code>@@@section delete bar</code>                  | An inherited section renders nothing — heading included — but stays addressable ( <code>parent.bar</code> ) and anchorable ( <code>after bar</code> ) |

A section name is an IDENTIFIER and it is checked: a letter, then letters, digits and `_` — never a hyphen, never a space. A stray token after the name that is not a placement clause is `INVALID_SYNTAX`, not silently dropped.

## 2.4 — Transparent, deleted, empty

- `@@@section (<name>)` — the parentheses enclose the NAME. The same mark may instead be asked for at the include — `@@@include (<reference>)` — and the two OR together. The name stays MANDATORY: a transparent section is a section in every other respect (toggle, placement, inheritance, override) — only its heading is withheld.
- **Transparency propagates to what the section governs.** Under a transparent container a sub-section emits neither ATX marker nor title: its RANK alone ( `1.` , `2.` ), which marks the sequence. The title is not lost — it reappears the moment a descendant NAMES the container by redeclaring it without the parentheses. That pairing is the sharing idiom: a parent ships a titleless bundle, each child titles it.
- The IMPLICIT section governs like a transparent one — it emits no heading either, so what it receives emits none.
- `@@@section delete <name>` — valid ONLY on an INHERITED section (removing one's own is simply not writing it: `DELETE_OF_UNINHERITED_SECTION` ). Exclusive with `virtual` ; a `final` section forbids it; on a container it carries the whole subtree; a descendant may resurrect it. It renders nothing at all, yet stays addressable — which is how the removed content gets re-placed elsewhere, with `@@@include parent.<name>` .
- **An empty section is an error** ( `EMPTY_SECTION` ). Emptying an override was the de-facto way to suppress inherited content, silently; `delete` says it out loud, so the mute form has no reason to exist. Exempt: a container, a `virtual` or `delete` section, every section of a `virtual` prompt.

## 2.5 — Pulling sub-sections : the merge

An `@@@include` that targets a section WITH sub-sections, or a sub-section itself, does not splice a block of its own: what it carries JOINS the list of the section that receives it, and that HOST governs it.

- **One numbering**, straight through — `1. 2. 3.` — however many templates contributed. A contribution never restarts at 1.
- **The pulled container's heading is absorbed**: the caller already named the section that receives it.
- **Transparency comes from the host**, not from the source.
- **Order is the order of the source**; the host's own sub-sections follow.
- **Same name is an OVERRIDE**, the same rule as under inheritance: the arriving entry replaces the one already there, keeping its SLOT and replacing its BODY, and what is covered is not rendered.

An `@@@include` is NOT a body, so a section that has sub-sections may carry the includes that feed it. What such an include BRINGS is judged once inserted: rendered TEXT landing in a list of sub-sections is `SECTION_WITH_SUBSECTIONS_HAS_BODY`, at phase 8.

## 2.6 — What it renders to

| Source                                              | Output                                                        |
|-----------------------------------------------------|---------------------------------------------------------------|
| <code>@@@section objectif</code>                    | <code>## Objectif</code> — the NAME, first letter upper-cased |
| <code>@@@section objectif : But de l'analyse</code> | <code>## Objectif</code> — the description is NOT rendered    |
| <code>@@@section rules : ## Règle finale</code>     | <code>## Rules</code> — a marker in a description is inert    |

| Source                                                      | Output                                                                                    |
|-------------------------------------------------------------|-------------------------------------------------------------------------------------------|
| <code>@@@section steps.one :</code><br><code>Lecture</code> | <code>### 1. Lecture</code> — rank among the RETAINED items of <code>steps</code>         |
| <code>@@@section steps.1</code>                             | <code>### 1.</code> — an index-named item adds no title                                   |
| an included prompt                                          | no <code>#</code> of its own ; its sections keep their <code>##</code> / <code>###</code> |
| <code>@@@{include x}</code> (inflowing)                     | a phrase spliced mid-line — NO heading at any depth                                       |
| a prompt with no <code>@@@section</code>                    | no heading at all                                                                         |
| a Level 0 prompt                                            | no heading at all                                                                         |

Levels 1 to 3 are RESERVED where the structure emits them — **inside a declared section** : a body line opening one (`#`, `##`, `###` + space/tab/end-of-line) is `INVALID_SYNTAX` ; make it a section of its own. **Unstructured body content is outside the rule** (L0, a prompt with no declared section, the implicit `_main`) : nothing is emitted for it, so a plain Markdown document stays a valid prompt — an identity header declares no structure. A marker in a `: description` is inert — neither emitted nor refused. `####` and deeper are ordinary body text ; so is a non-marker `#` (`C# rules`, `#tag`, `issue #12`) ; `@@@verbatim` is not processed at all, and a fenced code block (``` or `~~~`) is code — a `#`` line inside it is emitted verbatim. Exactly one blank line surrounds each emitted heading — everything else is byte-exact.

## 2.7 — Override rules

- Each declaration is read in full at its inheritance level : modifier, toggle, description all replace the parent's.
- A descendant's override is CONSTRAINED : it may only ADD a toggle to a plain section or RELAX default polarity (`! → ?`). It

MUST NOT drop an existing `?/!`, change `?→!`, or turn a defaulted-OFF section always-ON — any of these raises `OVER-RIDE_CONTRACT_VIOLATION`.

- The renderer uses the **most-derived declaration** in the chain for the effective toggle, description and body — whether that declaration is concrete OR virtual. A re-abstracted (virtual) leaf does not resurface an older concrete body; it raises `UNIMPLEMENTED_VIRTUAL_SECTION`.
- `@@@include parent.<section>` written INSIDE the body of `<section>` substitutes only the **body** — it is the same member’s shadowed content, so the heading stays the child’s, once. Written ANYWHERE ELSE it names a section that lives elsewhere and arrives with its heading.
- `@@@include <prompt>.<section>` brings a DIFFERENT section: it emits that section’s own heading at the splice point (never the raw markers).
- The **bounded** form `@@@{include ...}` never emits a heading, whatever it targets: it splices a PHRASE at the marker, and a block-level heading in mid-sentence would break the line it exists to keep.

## 2.8 — Errors

| Error                             | Trigger                                                                                                                                                                                                                 |
|-----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| INVALID_SYNTAX                    | Both <code>virtual</code> and <code>final</code> on the same section; bare <code>@@@virtual</code> / <code>@@@final</code> ; a body-text line opening a level 1-3 markdown heading (reserved to the rendered structure) |
| SECTION_WITH_SUBSECTIONS_HAS_BODY | A container section (one with sub-sections) carries a body of its own                                                                                                                                                   |

| Error                         | Trigger                                                                                                         |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------|
| VIRTUAL_SECTION_HAS_BODY      | A <code>virtual</code> section is followed by non-empty content (other than whitespace/inline comments)         |
| OVERRIDE_OF_FINAL_SECTION     | Descendant redeclares a <code>final</code> section                                                              |
| OVERRIDE_CONTRACT_VIOLATION   | An override drops/tightens a toggle (removes <code>? / !</code> , <code>? → !</code> , defaulted-OFF→always-ON) |
| UNIMPLEMENTED_VIRTUAL_SECTION | A <code>virtual</code> section remains unimplemented at the leaf                                                |
| INVALID_SECTION_PLACEMENT     | Placement clause on an override, or in a prompt with no <code>inherits</code> parent                            |
| INVALID_SECTION_ANCHOR        | <code>before / after</code> anchor is not an inherited section                                                  |
| INCLUDE_OF_VIRTUAL_SECTION    | An <code>include</code> resolves to a <code>virtual</code> section (no body to substitute)                      |

# Section III — Parameters and constants

## 3.1 — Parameter syntax

```
@@@param[?] <name> [: <type>][(<options>)] [<constraints>] [= <default>]
```

| Field       | Notes                                                                                                                                                                                             |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ?           | Optional. Glued to <code>param</code> . An OPTIONAL parameter MUST carry a <code>= &lt;default&gt;</code> (absent binding falls back to it). A required parameter without binding is an error.    |
| name        | Unicode letters, digits, <code>_</code> (case- and diacritic-insensitive). Must not collide with a reserved system-variable name ( <code>SYSTEM_VARIABLE_OVERRIDE</code> ).                       |
| type        | OPTIONAL — omitted, it defaults to <code>text</code> . One of: <code>text</code> , <code>textarea</code> , <code>number</code> , <code>date</code> , <code>boolean</code> , <code>select</code> . |
| options     | Required for <code>select</code> : <code>select("a", "b", "c")</code> .                                                                                                                           |
| constraints | Space-separated <code>key=value</code> pairs (see below).                                                                                                                                         |
| default     | Literal of the right type. Optional for a required parameter; MANDATORY when <code>?</code> is present.                                                                                           |
| label       | Optional UI label. Comma + quoted form: <code>, "Label text"</code> .                                                                                                                             |

## 3.2 — Standard types

| Type              | Stored as          | UI hint    |
|-------------------|--------------------|------------|
| <code>text</code> | Single-line string | Text input |

| Type     | Stored as               | UI hint           |
|----------|-------------------------|-------------------|
| textarea | Multi-line string       | Text area         |
| number   | Integer or decimal      | Number input      |
| date     | YYYY-MM-DD              | Date picker       |
| boolean  | true / false            | Checkbox / toggle |
| select   | One of declared options | Dropdown          |

### 3.3 — Constraints

| Constraint        | Applies to     | Effect                     |
|-------------------|----------------|----------------------------|
| min=<n>           | number         | Lower bound (inclusive)    |
| max=<n>           | number         | Upper bound (inclusive)    |
| minlen=<n>        | text, textarea | Minimum char count         |
| maxlen=<n>        | text, textarea | Maximum char count         |
| pattern="<regex>" | text, textarea | Value must match the regex |

Violation raises `CONSTRAINT_VIOLATION`.

### 3.4 — Examples

```

@@@param client_name : text, "Client name"
@@@param? notes : textarea maxlen=500 = "", "Additional notes"
@@@param age : number min=0 max=150 = 25, "Age"
@@@param lang : select("en", "fr", "de") = "en", "Language"
@@@param code : text pattern="[A-Z]{3}-[0-9]{4}" = "ABC-0001"

```

### 3.5 — Usage in body

```
Hello @@@=client_name, your code is @@@=code.
```

### 3.6 — Constants

```
@@@const <NAME> : <type> = <value> [, "<label>"]
```

| Property | Notes                                                            |
|----------|------------------------------------------------------------------|
| NAME     | Uppercase by convention (not enforced).                          |
| type     | Required (same six types as <code>param</code> ).                |
| value    | Required (no « no default » form — constants must have a value). |
| label    | Optional.                                                        |

Constants are immutable after definition. They do NOT appear in the parameter dialog at instantiation. A constant can be promoted to a parameter and vice versa.

### 3.7 — Override at include site

```
@@@include <prompt>(name=value, name2="value 2")
```

The bindings override the target's parameter defaults for this substitution only. They do NOT mutate the target's defaults. Passing a name the target does not declare is an UNDECLARED\_INCLUDE\_PARAMETER error (the same code for `self` / `parent`).

## Section IV — Attachments

### 4.1 — Syntax

```
@@@attachment[?] <name> : <type> fixed file    "<path>"
@@@attachment[?] <name> : <type> fixed blob    "<data_uri>"
@@@attachment[?] <name> : <type> fixed record "<external_ref>"
@@@attachment[?] <name> : <type> to-include, "<description>"
```

| Field                    | Notes                                                                                                                                                                                              |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>?</code>           | Optional flavour (only meaningful with <code>to-include</code> ).<br>Glued to <code>attachment</code> .                                                                                            |
| <code>name</code>        | Alphanumeric, underscore.                                                                                                                                                                          |
| <code>type</code>        | MIME type or file extension ( <code>pdf</code> , <code>png</code> , <code>csv</code> , ...).                                                                                                       |
| <code>when</code>        | Binding time: <code>fixed</code> (bound at definition) or <code>to-include</code> (provided at instantiation).                                                                                     |
| <code>source</code>      | Only with <code>fixed</code> — where the content lives: <code>file</code> (path), <code>blob</code> (data URI), <code>record</code> (external store ref). Forbidden with <code>to-include</code> . |
| <code>value</code>       | With <code>fixed</code> : a quoted file path, <code>data:&lt;mime&gt;;base64,&lt;payload&gt;</code> URI (RFC 2397), or external-store ref. Absent for <code>to-include</code> .                    |
| <code>description</code> | For <code>to-include</code> : user-facing text. Comma + quoted form.                                                                                                                               |

### 4.2 — The two axes at a glance

WHEN (binding time) and, for `fixed` only, SOURCE (where the content lives).

| When        | Source               | Bound                 | Required by default          | Use case                            |
|-------------|----------------------|-----------------------|------------------------------|-------------------------------------|
| fixed       | file / blob / record | At definition time    | n/a (always present)         | Style guides, reference docs, logos |
| to-include  | — (none)             | At instantiation time | Yes — error if not provided  | User documents, varying data        |
| to-include? | — (none)             | At instantiation time | No — absent is a valid state | Optional context files              |

### 4.3 — Position

`attachment` declarations SHOULD live at the END of the prompt (after all content). Convention only ; processors accept any order.

### 4.4 — Examples

```

@@@attachment manual : pdf fixed file "docs/manual.pdf"
@@@attachment logo : png fixed blob "..."
@@@attachment data : csv to-include, "Data file to process"
@@@attachment? notes : txt to-include, "Additional notes"

```

### 4.5 — Errors

| Error                | Trigger                                                                                            |
|----------------------|----------------------------------------------------------------------------------------------------|
| ATTACHMENT_NOT_FOUND | A <code>fixed file / record</code> source cannot be resolved (path or external ref does not exist) |
| ATTACHMENT_REQUIRED  | Required <code>to-include</code> attachment not provided at instantiation                          |

## Section V — Includes and inheritance

### 5.1 — Inheritance (`inherits`)

```
@@@template <id> inherits <parent_id>
```

Inheritance is an inline `inherits` clause on the `@@@template` header — there is no standalone `@@@inherits` directive. Single inheritance only. Cycles forbidden ( `CIRCULAR_INHERITANCE` ). Multiple levels allowed.

### 5.2 — Include — basic forms

| Form                                             | Effect                                                                                                                                                             |
|--------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>@@@{include &lt;id&gt;}</code>             | Splice the resolved content of prompt <code>&lt;id&gt;</code> .                                                                                                    |
| <code>@@@{include &lt;path/to/id&gt;}</code>     | Same, with hierarchical path.                                                                                                                                      |
| <code>@@@{include &lt;id&gt;(p=v, q="w")}</code> | Same + parameter bindings (override defaults for this site only).                                                                                                  |
| <code>@@@include (&lt;reference&gt;)</code>      | Same target, rendered with NO heading of its own. The parentheses wrap the WHOLE reference, arguments included: <code>@@@include (welcome(lang=fr).intro)</code> . |

## 5.3 — `self` and `parent` references

| Form                                                 | Returns                                                                                                                                            |
|------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>parent</code>                                  | The full resolved content of the parent prompt (all sections, in declaration order).                                                               |
| <code>parent.&lt;section&gt;</code>                  | That section AS THE PARENT RESOLVES IT — the parent’s own declaration, or the nearest one it inherits. The current prompt’s override is skipped.   |
| <code>parent.&lt;section&gt;.&lt;sub&gt;</code>      | A named sub-section of that section.                                                                                                               |
| <code>parent.&lt;ancestor&gt;.&lt;section&gt;</code> | That section from a NAMED ancestor, resolved through the parent chain. <code>&lt;ancestor&gt;</code> MAY be a qualified handle.                    |
| <code>self.&lt;section&gt;</code>                    | The most specialized version of the section (current prompt or nearest ancestor).                                                                  |
| <code>self.&lt;ancestor&gt;.&lt;section&gt;</code>   | That section from a named ancestor — the chain starting at the CURRENT prompt, which is the only way to name this prompt’s own version explicitly. |

All forms accept parameter bindings: `include parent.task(format="json")`.

**The two axes differ by ONE thing: where the chain starts.** `self` starts at the current prompt, `parent` at its parent; everything else is identical, which is why the same arbitration governs both.

**`parent.a.b` and `self.a.b` have two readings, and neither is ranked:** the prompt’s sub-section `a.b`, or section `b` of the ancestor named `a`. Both are defined, so a processor resolves BOTH —

one match wins, two raise `AMBIGUOUS_INCLUDE`, and none raises `UNDEFINED_REFERENCE`. A reference that reaches nothing is an error, never silence.

`self / parent` (no `^`) address the **prompt** inheritance axis (OO #1). The **collection** axis (OO #2, L5) is a disjoint construct written with the unary prefix operator `^`: `^self / ^parent` (see chapter Collections). The two axes never share precedence — a bare name resolves the prompt axis only.

## 5.4 — What includes DO and DON'T substitute

- `include <prompt>` → substitutes the **full rendered body** of the prompt.
- `include parent.<section>` written INSIDE the body of `<section>` → the «extend what I override» idiom: it splices the body this declaration SHADOWS, into the section already being rendered, with **no heading of its own** — the heading is already there.
- The same reference written **anywhere else** names a section that lives elsewhere, and it arrives like any section-targeted include: **with its heading**, at the point of splice. The discriminator is the ENCLOSING section, not who wrote the reference.
- `include <prompt>.<section>` → same rule: a section reached through an include emits its heading at its point of splice. The section's toggle and the `@@@section` marker itself are never substituted.
- **The bounded form `@@@{include ...}` never emits a heading**, whatever it targets — it splices a PHRASE at the marker, and only the full-LINE form carries structure. Everything above about headings concerns the line form.
- **And a phrase is one line.** What the bounded form splices is TRIMMED, then every run of whitespace containing a line ending collapses to exactly ONE space; the splice itself adds nothing. Prefix `@@@{include frag}` suffix renders Prefix XYZ suffix — one space, not two, because the trim removes the tar-

get’s own trailing line ending. A run of spaces with no line ending is left as the author wrote it, and an include sitting at END OF LINE is unchanged.

- **@@@include (<reference>)** asks for a transparent render — the consumer-side half of `@@@section (<name>)`, and the LOGICAL OR of the two: declared, asked for, or both give the same text. It is INERT on a target already transparent and on material that merges into the host list. On a whole TEMPLATE it is `TRANSPARENT_INCLUDE_ON_TEMPLATE` — an included prompt emits no heading of its own, so there would be nothing to withhold.
- An include that targets a section WITH sub-sections, or a sub-section → **the merge**: what it carries joins the host section’s list, numbered once straight through, the pulled container’s heading absorbed (see Sections). This does not depend on the SPELLING — `lot.list`, `parent.list`, `self.list` and `^self.lot.list` behave identically.
- `include` resolved to a `virtual` section → `INCLUDE_OF_VIRTUAL_SECTION` (nothing to substitute).

## 5.5 — Resolution order

1. The target prompt resolves its own inheritance chain independently.
2. The target’s parameter defaults are determined by its deepest declaration.
3. The include site can override those defaults via `(name=value)` — for this substitution only; the target’s defaults are not mutated.

## 5.6 — Errors

| Error                | Trigger                                                        |
|----------------------|----------------------------------------------------------------|
| CIRCULAR_INHERITANCE | A prompt’s <code>inherits</code> chain reaches back to itself. |

| Error                           | Trigger                                                                         |
|---------------------------------|---------------------------------------------------------------------------------|
| CIRCULAR_INCLUDE                | An include cycle is detected during Phase 8.                                    |
| UNDEFINED_REFERENCE             | <code>inherits</code> or <code>include</code> targets a non-existent prompt id. |
| IN-<br>CLUDE_OF_VIRTUAL_SECTION | <code>include</code> resolves to a <code>virtual</code> section (no body).      |

## Section VI — Collections

### 6.1 — Declaration and membership

```
@@@collection <name> [inherits <parent_collection>]
@@@template <member_id>                                -- zero or more -- the public su
@@@end-collection
```

A collection is declared in-language by a `@@@collection <name>` block that lists its public members. There is NO `kind` flag and NO sidecar: an entity is a collection precisely *because* a `@@@collection` block declares it; a plain folder is just storage and declares nothing. Collection inheritance is the inline `inherits` clause on the `@@@collection` header.

Collections NEST by containment, to UNBOUNDED depth. A member's qualified id is the dotted containment run of its holding collections plus the id: `<collection>{.<sub-collection>}.<template_id>`. A collection is a POO<sup>2</sup>L entity addressed with `.`; physical folders (addressed with `/`) are a separate, implicit layer.

### 6.2 — Membership (on the member's header)

```
@@@template <collection_name>.<template_id>
```

A prompt joins a collection by QUALIFYING its `@@@template` header id — there is no separate membership directive. Folder placement is physical and is never written in prompt text.

### 6.3 — Application-level metadata (outside prompt text)

| Field                                                                                            | Notes                                                                      |
|--------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------|
| <code>tags</code> , <code>description</code> ,<br><code>color</code> , <code>capabilities</code> | Organizational only. App-level extension ( §9.3 ); no effect on rendering. |

Tags, version history, permissions and the like MAY still live in application-level storage. Virtuality/finality is NOT such metadata — it is declared on the member’s `@@@template` header via the `virtual` / `final` modifier.

### 6.4 — Folder vs collection at a glance

| Aspect                                                     | Folder (no<br><code>@@@collection</code><br>block) | Collection ( <code>@@@collection</code><br>block)                                                   |
|------------------------------------------------------------|----------------------------------------------------|-----------------------------------------------------------------------------------------------------|
| Availability                                               | All levels (L0–L5)                                 | Level 5 only                                                                                        |
| Inheritance                                                | No                                                 | Yes ( inherits on the<br><code>@@@collection</code> header)                                         |
| Virtual / final members                                    | n/a                                                | Yes ( <code>virtual</code> / <code>final</code><br>modifier on member<br><code>@@@template</code> ) |
| Member override                                            | n/a                                                | Yes — derived collection<br>wins by prompt id                                                       |
| <code>^parent.&lt;template_id&gt;</code> (collection axis) | n/a                                                | Yes                                                                                                 |
| Sub-grouping / nesting                                     | Yes                                                | Yes (unbounded)                                                                                     |

## 6.5 — Collection-scoped references (L5)

The collection axis (OO #2) is written with the unary prefix operator `^` on the keyword — disjoint from the prompt axis ( `self` / `parent` ), with no precedence between them.

| Form                                                     | Effect                                                                                                                          |
|----------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <code>^parent.&lt;template_id&gt;</code>                 | Full content of <code>&lt;template_id&gt;</code> as resolved in the parent collection.                                          |
| <code>^parent.&lt;template_id&gt;.&lt;section&gt;</code> | That section's body in the parent collection.                                                                                   |
| <code>^self.&lt;template_id&gt;[.&lt;section&gt;]</code> | The current collection's effective <code>&lt;template_id&gt;</code> (its member override counterpart of <code>^parent</code> ). |
| <code>inherits ^parent.P</code>                          | The template-level OO chain of P as resolved in the parent collection (inline clause on the <code>@@@template</code> header).   |

## 6.6 — Template-level OO<sup>2</sup> markers

| Marker         | Form                                                     | Meaning                                                     |
|----------------|----------------------------------------------------------|-------------------------------------------------------------|
| Virtual prompt | <code>@@@template virtual &lt;coll&gt;.&lt;id&gt;</code> | Abstract member — derived collection MUST override by id.   |
| Final prompt   | <code>@@@template final &lt;coll&gt;.&lt;id&gt;</code>   | Sealed member — derived collection MUST NOT override by id. |

`virtual` / `final` are MODIFIERS on the member's `@@@template` header, never standalone directives (a bare `@@@virtual` / `@@@final` is `INVALID_SYNTAX`). Mutually exclusive — combining them is `INVALID_SYNTAX`.

### 6.7 — Errors

| Error                           | Trigger                                                                                                                             |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| CIRCULAR_COLLECTION_INHERITANCE | Collection <code>inherits</code> chain loops.                                                                                       |
| UNKNOWN_COLLECTION              | A <code>@@@collection inherits</code> clause names a target that no <code>@@@collection</code> block declares (e.g. only a folder). |
| UNIMPLEMENTED_VIRTUAL_TEMPLATE  | A <code>virtual</code> prompt has no concrete override at the leaf.                                                                 |
| OVERRIDE_OF_FINAL_TEMPLATE      | A derived collection redeclares a <code>final</code> prompt by id.                                                                  |

### 6.8 — The two axes are DISJOINT (no precedence)

There is NO fallback or precedence between axes — the `^` operator selects the axis unambiguously :

- `parent` / `self` (no `^`) → **prompt** inheritance axis (OO #1): the parent prompt / this prompt's own section.
- `^parent` / `^self` (with `^`) → **collection** inheritance axis (OO #2): the parent collection's member / this collection's effective member.

Because the axis is chosen syntactically, there is never ambiguity to resolve by ordering. An unresolved reference on either axis is `UNDEFINED_REFERENCE` .

## Section VII — System variables

Read-only values substituted automatically at Phase 9 (Parameter Substitution), without parameter plumbing.

### 7.1 — The twelve variables

| Variable                      | Format                     | Example                           |
|-------------------------------|----------------------------|-----------------------------------|
| <code>@@@=DATE</code>         | YYYY-MM-DD                 | <code>2026-05-18</code>           |
| <code>@@@=TIME</code>         | HH:MM:SS                   | <code>14:32:00</code>             |
| <code>@@@=DATETIME</code>     | ISO 8601, UTC              | <code>2026-05-18T14:32:00Z</code> |
| <code>@@@=YEAR</code>         | Integer                    | <code>2026</code>                 |
| <code>@@@=MONTH</code>        | 01-12                      | <code>05</code>                   |
| <code>@@@=DAY</code>          | 01-31                      | <code>18</code>                   |
| <code>@@@=WEEKDAY</code>      | Localized name             | <code>Monday</code>               |
| <code>@@@=USER</code>         | Display name               | <code>Jacques Lovi</code>         |
| <code>@@@=USERNAME</code>     | Login name (host-provided) | <code>jacques.lovi</code>         |
| <code>@@@=LANG</code>         | ISO code                   | <code>en</code>                   |
| <code>@@@=GROUPS</code>       | Comma-separated            | <code>dev, qa</code>              |
| <code>@@@=GROUPS_ADMIN</code> | Comma-separated            | <code>dev</code>                  |

The standard reserves twelve names ; the engine reserves eleven — `USERNAME` (login) has no meaning at engine level and is supplied by the host shell as an application-level value. All temporal values are UTC ; `WEEKDAY` is localized to the user's `LANG` .

## 7.2 — Substitution form — the `=` is mandatory

| Form                                      | Status                                                                               |
|-------------------------------------------|--------------------------------------------------------------------------------------|
| <code>@@@=NAME</code>                     | The ONE canonical form ( <code>@@@{= NAME }</code> is the same, spaced).             |
| <code>@@@NAME</code> (no <code>=</code> ) | NOT a substitution — a bare <code>@@@NAME</code> is a line directive / syntax error. |
| <code>{{NAME}}</code>                     | Does NOT exist anywhere in POO <sup>2</sup> L.                                       |

There is no «dashboard» template layer: `@@@=NAME` is the only way to reach a system variable, in body text exactly like a parameter reference.

## 7.3 — Rules

- System variables are **read-only** — the author cannot declare them.
- Declaring a `@@@param` / `@@@const` whose name collides with a system variable raises `SYSTEM_VARIABLE_OVERRIDE` : the substitution always resolves to the system value, so the declaration could never take effect.
- Implementations resolve system variables from the rendering context (the user's locale, group membership, current UTC time).

## Section VIII — Comments and verbatim

### 8.1 — Line and bounded comment

```
@@@-- some comment text
```

Line comment, runs to the end of the line. For a comment in the middle of running text, use the bounded form (any bracket family, run count raisable) :

```
@@@(-- some comment text )
```

Removed at instantiation. The bounded form may span multiple lines. Both forms are opaque (the sigil `@@@` is inert inside them) and non-nesting ; for nesting use a block comment.

Any DIRECTIVE line (e.g. `@@@section` , `@@@param` ) MAY also carry a trailing `--` tail comment, which runs to the end of that line and is stripped like a line comment.

### 8.2 — Block comment

```
@@@comment  
multi-line text  
@@@end-comment
```

Removed at instantiation. Multi-line is the use case. Nestable.

### 8.3 — Verbatim

```
@@@verbatim
text that is NOT interpreted as POO²L
@@@end-verbatim
```

| Property            | Behaviour                                                                       |
|---------------------|---------------------------------------------------------------------------------|
| Output              | Kept in the rendered output (unlike comments)                                   |
| POO²L syntax inside | NOT processed (parameters, includes, sections etc. are passed through verbatim) |
| Nesting             | Yes (depth-tracked)                                                             |
| Use case            | Meta-templates, documentation of POO²L syntax, escaping                         |

### 8.4 — When to use what

| Need                                                         | Use                                                                                             |
|--------------------------------------------------------------|-------------------------------------------------------------------------------------------------|
| Hide a note from the AI but keep it visible to the author    | Comment (inline or block)                                                                       |
| Show POO²L syntax literally (e.g. teach POO²L from a prompt) | Verbatim                                                                                        |
| Temporarily disable a chunk of prompt prose                  | Block comment around it                                                                         |
| Document a code snippet inside the body                      | Indented code block (regular Markdown) — comments and verbatim are POO²L-specific, not Markdown |

## Section IX — Resolution phases

POO<sup>2</sup>L renderers execute eleven numbered phases in this fixed order, plus one sub-phase (3.b) that the pack never pins as a bare integer.

| # | Phase                   | Does                                                                                    | Errors raised                                                                                                                                                                                                                                                                                                             |
|---|-------------------------|-----------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1 | Parsing                 | Tokenize, parse AST, extract in-line declarations, register aliases, check deprecation. | <code>INVALID_SYNTAX</code> , <code>DUPLICATE_DECLARATION</code> , <code>ALIAS_CONFLICT</code> , <code>VIRTUAL_SECTION_HAS_BODY</code> , <code>VIRTUAL_TEMPLATE_HAS_BODY</code> , <code>SECTION_WITH_SUBSECTIONS_HAS_BODY</code> , <code>DEPRECATED_TEMPLATE</code> (warning), <code>MISSING_DESCRIPTION</code> (warning) |
| 2 | Collection context (L5) | Resolve collection inheritance, compute effective prompt set, validate virtuals/finals. | <code>CIRCULAR_COLLECTION_INHERITANCE</code> , <code>CIRCULAR_LIBRARY_DEPENDENCY</code> , <code>UNKNOWN_COLLECTION</code> , <code>AMBIGUOUS_COLLECTION</code> , <code>UNIMPLEMENTED_VIRTUAL_TEMPLATE</code> , <code>OVERVERRIDE_OF_FINAL_TEMPLATE</code> , <code>UNDEFINED_REFERENCE</code>                               |
| 3 | Inheritance resolution  | Resolve the inline inherits chain, merge sections, apply overrides.                     | <code>CIRCULAR_INHERITANCE</code> , <code>OVERVERRIDE_OF_FINAL_SECTION</code> , <code>UNIMPLEMENTED_VIRTUAL_SECTION</code> , <code>INVALID_SECTION_PLACEMENT</code> , <code>INVALID_SECTION_ANCHOR</code> , <code>SECTION_SHAPE_MISMATCH</code> , <code>UNDEFINED_REFERENCE</code>                                        |

| #   | Phase             | Does                                                                                                                                                                                       | Errors raised                                                                               |
|-----|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------|
| 3.b | Call contract     | On every public override (both axes), validate the effective signature against the target's: names/ types, select lists, required set, constraint monotonicity, and toggle-input survival. | VIRTUAL_SIGNATURE_MISMATCH ,<br>OVERRIDE_CONTRACT_VIOLATION                                 |
| 4   | Section selection | Apply the ? / ! toggle map ; mark OFF sections inert.                                                                                                                                      | —                                                                                           |
| 5   | Parameter binding | Resolve constants (hoisted), apply the selected parameter set, then explicit values, then defaults.                                                                                        | TYPE_MISMATCH ,<br>CONSTRAINT_VIOLATION ,<br>SELECT_INVALID_OPTION ,<br>UNDEFINED_REFERENCE |

| #  | Phase                  | Does                                                                                              | Errors raised                                                                                                                                                                                              |
|----|------------------------|---------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 6  | Constant resolution    | Confirm constant resolution, validate immutability.                                               | IMMUTABILITY_VIOLATION ,<br>TYPE_MISMATCH (constants),<br>UNDEFINED_REFERENCE                                                                                                                              |
| 7  | Attachment binding     | Validate fixed paths, bind to-include files.                                                      | ATTACHMENT_NOT_FOUND , ATTACHMENT_REQUIRED                                                                                                                                                                 |
| 8  | Include resolution     | Resolve and substitute include targets, detect cycles.                                            | CIRCULAR_INCLUDE , AMBIGUOUS_INCLUDE , UNDECLARED_INCLUDE_PARAMETER , INCLUDE_OF_VIRTUAL_SECTION ,<br>NOT_EXPORTED , TYPE_MISMATCH ,<br>CONSTRAINT_VIOLATION , SELECT_INVALID_OPTION , UNDEFINED_REFERENCE |
| 9  | Parameter substitution | Substitute @@@=name references and system variables.                                              | UNDEFINED_PARAMETER , UNDEFINED_REFERENCE                                                                                                                                                                  |
| 10 | Assertion evaluation   | Validate scope nesting; evaluate @@@assert predicates against rendered content; block on failure. | MALFORMED_SCOPE , ASSERTION_FAILED , INVALID_ASSERTION                                                                                                                                                     |

| #  | Phase             | Does                                                                                                                                                                                                    | Errors raised           |
|----|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------|
| 11 | Output generation | Strip processing directives (incl. <code>@@@scope</code> ), emit final text with its structure headings ( <code>##</code> section, <code>###&lt;n&gt;.</code> subsection; the prompt contributes none). | RESOURCE_LIMIT_EXCEEDED |

## 9.1 — Determinism

For a given prompt + parameter bindings, the eleven-phase pipeline produces **the same output** on any conformant L5 implementation. That is POO<sup>2</sup>L's interoperability promise.

## 9.2 — Order matters

A few common confusions cleared up :

- **Inheritance resolves BEFORE constants.** A constant's value is fixed at the prompt that declares it (resolved at the start of Phase 5); inherited templates see the same value.
- **Includes resolve AFTER inheritance.** So a child's body, including inherited sections, can contain includes that get expanded later (Phase 8 follows Phase 3).
- **Parameters substitute LAST.** Any parameter reference in any included or inherited fragment is substituted once the whole skeleton is assembled (Phase 9).

- **System variables substitute in Phase 9** (along with parameters); they cannot be overridden by parameter sets or include-site bindings.

## Section X — Error catalog

### 10.1 — Errors (the renderer MUST raise) — all 56

Grouped by the phase that raises each. A/B = raisable in either phase.

#### Phase 1 — Parsing / declaration

| Code                    | Meaning                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| INVALID_BOUNDED_KEYWORD | A bounded form ( <code>@@@( ... )</code> and its three sibling families) carries a keyword that does not exist there — only <code>= name</code> , <code>include</code> , <code>--</code> and <code>verbatim</code> do. <code>section</code> , <code>name</code> , <code>param...</code> exist in LINE form only. Never re-emitted as text: the escape for a literal sigil is <code>@@@@</code> |
| INVALID_SYNTAX          | Malformed construct; both <code>virtual + final</code> ; bare <code>@@@virtual / @@@final</code> ; rendering content outside a section; a body-text line opening a level 1-3 markdown heading (reserved to the rendered structure); malformed blob URI                                                                                                                                         |

| Code                                           | Meaning                                                                                                                                                                             |
|------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>DUPLICATE_DECLARATION</code>             | A single-valued directive repeats, or two declarations collide on one name in a frame (param/const, sections, attachments, sets, listings)                                          |
| <code>ALIAS_CONFLICT</code>                    | A <code>@@@alias</code> collides with an existing id or another alias                                                                                                               |
| <code>USES_ALIAS_CONFLICT</code>               | Two <code>@@@uses ... as &lt;alias&gt;</code> in one prompt bind the same local alias                                                                                               |
| <code>VIRTUAL_SECTION_HAS_BODY</code>          | A virtual section owns rendered body before the next section                                                                                                                        |
| <code>VIRTUAL_TEMPLATE_HAS_BODY</code>         | A virtual prompt carries rendered material                                                                                                                                          |
| <code>SECTION_WITH_SUBSECTIONS_HAS_BODY</code> | A container section (has sub-sections) carries a body of its own. An <code>@@@include</code> is NOT a body: what it BRINGS into such a section is judged at 8, under this same code |
| <code>DELETED_SECTION_HAS_BODY</code>          | A <code>@@@section delete</code> is followed by rendered material — it renders nothing, so that material would be lost                                                              |

| Code                               | Meaning                                                                                                                                                                                                                                                                                |
|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TOGGLE_SECTION_WITHOUT_DESCRIPTION | A <code>@@@section?</code> or <code>@@@section!</code> carries no : description . A toggleable section is offered in the instantiation dialog, and the description is the only prose that dialog can show for it (the description is never rendered — the heading comes from the name) |
| EMPTY_SECTION (also 3)             | A section definition carries no rendered material. Exempt: a container, a <code>virtual</code> or <code>delete</code> section, every section of a <code>virtual</code> prompt. At 1 for a prompt that inherits nothing, at 3 otherwise — containment can be inherited                  |
| INVALID_CONSTRAINT                 | A constraint DECLARATION is malformed (wrong type, min>max , bad pattern , duplicate key)                                                                                                                                                                                              |
| SYSTEM_VARIABLE_OVERRIDE           | A <code>@@@param / @@@const</code> (or bind) collides with a reserved system-variable name                                                                                                                                                                                             |
| INVALID_ASSERTION (also 10)        | An <code>@@@assert</code> predicate is malformed (literal at 1, post-substitution at 10)                                                                                                                                                                                               |

## Phase 2 — Collection context (L5)

| Code                              | Meaning                                                                        |
|-----------------------------------|--------------------------------------------------------------------------------|
| CIRCU-LAR_COLLEC-TION_INHERITANCE | Collection inherits chain loops                                                |
| CIRCU-LAR_LIBRARY_DEPENDENCY      | Library dependency chain loops                                                 |
| UNKNOWN_COLLECTION                | A @@@collection inherits clause names a target no @@@collection block declares |
| AMBIGUOUS_COLLECTION              | A collection reference resolves to more than one collection                    |
| EX-PORT_OF_UNKNOWN_MEMBER         | A collection exports a member it does not declare                              |
| UNIMPLEMEN-TED_VIRTUAL_TEMPLATE   | A virtual prompt has no concrete override at the leaf                          |
| OVER-RIDE_OF_FINAL_TEMPLATE       | A derived collection redeclares a final prompt by id                           |

## Phase 3 — Template inheritance

| Code                           | Meaning                                                |
|--------------------------------|--------------------------------------------------------|
| CIRCULAR_INHERITANCE           | Template inherits chain loops                          |
| OVER-RIDE_OF_FINAL_SECTION     | A descendant redeclares a final section                |
| UNIMPLEMEN-TED_VIRTUAL_SECTION | A virtual section has no concrete override at the leaf |

| Code                           | Meaning                                                                                                                               |
|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| INVA-LID_SECTION_PLACEMENT     | Placement clause on an override, or in a prompt with no <code>inherits</code> parent                                                  |
| INVA-LID_SECTION_ANCHOR        | <code>before / after</code> anchor is not an inherited section                                                                        |
| DELETE_OF_UNINHHERITED_SECTION | <code>@@@section delete &lt;name&gt;</code> names a section the prompt does not inherit — removing one's own is simply not writing it |
| SECTION_SHAPE_MISMATCH         | An override flips a section leaf↔container                                                                                            |
| EXPORT_OF_UNKNOWN_SECTION      | A prompt exports a section it does not declare                                                                                        |

### Phase 3.b — Call contract (every public override, both axes)

| Code                         | Meaning                                                                                                          |
|------------------------------|------------------------------------------------------------------------------------------------------------------|
| OVER-RIDE_CONTRACT_VIOLATION | An override breaches the target contract (toggle monotonicity, param/constraint relaxation) — non-virtual target |
| VIRTUAL_SIGNATURE_MISMATCH   | Same, where the override target is a virtual prompt                                                              |

### Phase 4 — Section selection

| Code                             | Meaning                                                                          |
|----------------------------------|----------------------------------------------------------------------------------|
| UNK-<br>NOWN_SEC-<br>TION_TOGGLE | A toggle-map entry names a non-existent or non-togglable section                 |
| UNKNOWN_FRAME                    | An instantiation entry's frame-id diverges from the resolved active frame schema |

## Phase 5 — Parameter binding

| Code                                         | Meaning                                                                                                                                        |
|----------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| UNKNOWN_PARAMETER_SET                        | A selected parameter-set name matches no visible <code>@@@parameter-set</code>                                                                 |
| UNDECLA-<br>RED_INSTANTIA-<br>TION_PARAMETER | A top-level input names a parameter the prompt does not declare                                                                                |
| UNDECLA-<br>RED_PARAMETER_SET_BINDING        | A parameter set binds a parameter the prompt does not declare                                                                                  |
| TYPE_MISMATCH (also 6, 8)                    | A typed value/default/binding does not match its declared type                                                                                 |
| CONSTRAINT_VIOLATION (also 6, 8)             | A value violates a valid constraint ( <code>min</code> , <code>max</code> , <code>minlen</code> , <code>maxlen</code> , <code>pattern</code> ) |
| SELECT_INVALID_OPTION (also 6, 8)            | A value is not in a <code>select</code> 's declared options                                                                                    |

## Phase 6 — Constant resolution

| Code                        | Meaning                                                           |
|-----------------------------|-------------------------------------------------------------------|
| IMMUTABILI-<br>TY_VIOLATION | An instantiation supplies a binding for a <code>const</code> name |

## Phase 7 — Attachment binding

| Code                          | Meaning                                                                    |
|-------------------------------|----------------------------------------------------------------------------|
| ATTACHMENT_NOT_FOUND          | A fixed file / record source cannot be resolved                            |
| ATTACHMENT_REQUIRED           | A required to-include attachment is not provided                           |
| UNDECLARED_ATTACHMENT_BINDING | A supplied to-include name matches no declared attachment of a valid frame |

## Phase 8 — Include resolution

| Code                         | Meaning                                                                                   |
|------------------------------|-------------------------------------------------------------------------------------------|
| CIRCULAR_INCLUDE             | An include cycle is detected                                                              |
| AMBIGUOUS_INCLUDE            | An include reference resolves to more than one entity                                     |
| AMBIGUOUS_ENTITY             | A reference resolves to more than one entity during lookup                                |
| AMBIGUOUS_USES_TARGET        | A @@@uses target resolves to more than one entity                                         |
| UNDEFINED_USES_TARGET        | A @@@uses target resolves to no entity                                                    |
| UNDECLARED_INCLUDE_PARAMETER | A binding passed to include / self / parent names a parameter the target does not declare |
| INCLUDE_OF_VIRTUAL_SECTION   | An include resolves to a virtual section (no body)                                        |

| Code                            | Meaning                                                                                                                                                                                                                             |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NOT_EXPORTED                    | An external reference names a member/section not on the public surface (visibility gate resolved at reference/include time)                                                                                                         |
| UNENUMERABLE_INCLUDE_TARGET     | An indirect target ( <code>@@@include @@@=name</code> ) names a symbol whose domain is not declared and finite — only a <code>select</code> parameter or a constant may, so the include graph stays analysable before instantiation |
| TRANSPARENT_INCLUDE_ON_TEMPLATE | <code>@@@include (x)</code> asks for a transparent render but <code>x</code> is a whole prompt, which emits no heading of its own — mark the sections one by one, or target one section                                             |

## Phase 9 — Parameter substitution

| Code                             | Meaning                                                                                   |
|----------------------------------|-------------------------------------------------------------------------------------------|
| UNDEFINED_PARAMETER              | A declared non-optional parameter with no default is left unbound                         |
| UNDEFINED_REFERENCE (also 2/3/8) | An inherits/include/collection-ref/ <code>@@@=name</code> points to a non-existent target |

## Phase 10 — Assertion evaluation

| Code             | Meaning                                                                          |
|------------------|----------------------------------------------------------------------------------|
| ASSERTION_FAILED | A blocking <code>@@@assert</code> predicate is not satisfied by rendered content |

| Code             | Meaning                                                                             |
|------------------|-------------------------------------------------------------------------------------|
| MALFOR-MED_SCOPE | A <code>@@@scope</code> partially overlaps section boundaries (not properly nested) |

## Phase 11 — Output generation

| Code                     | Meaning                                                                                                   |
|--------------------------|-----------------------------------------------------------------------------------------------------------|
| RE-SOURCE_LIMIT_EXCEEDED | A published implementation limit was reached (nesting depth, chain length, attachment size, member count) |

## 10.2 — Warnings (advisory; never part of the conformance SHALL set)

| Code                     | Trigger                                                                                                                                                         |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MISSING_DESCRIPTION      | A structured prompt declares <code>@@@template</code> + <code>@@@name</code> but omits the OPTIONAL <code>@@@description</code> . Advisory only — never blocks. |
| DEPRECATED_TEMPLATE      | A <code>@@@deprecated</code> prompt is instantiated, included, or inherited. The migration message SHOULD be surfaced.                                          |
| PARAMETER_NAME_IS_PREFIX | A declared name is a strict prefix of another; an implicit <code>@@@=name</code> binds the longest match. Use <code>@@@{= name }</code> to disambiguate.        |

A warning NEVER blocks rendering in the baseline semantics, and *how* a processor handles one is implementation latitude (ignore / surface / elevate to a blocking error in a documented stricter mode). The three WARNING conditions are NOT part of the conformance SHALL set.

## 10.3 — Counts

- **52 ERROR conditions** span Phases 1-11 (plus sub-phase 3.b) — the full §6.2 catalog. Several codes are raisable in more than one phase ( `UNDEFINED_REFERENCE` , `TYPE_MISMATCH` , `CONSTRAINT_VIOLATION` , `SELECT_INVALID_OPTION` , `INVALID_ASSERTION` ).
- **3 WARNING conditions** ( `MISSING_DESCRIPTION` , `DEPRECATED_TEMPLATE` , `PARAMETER_NAME_IS_PREFIX` ) — advisory, never part of the conformance SHALL set.

# Section XI — Conformance levels

A conforming implementation declares a single level  $N$  ( $1 \leq N \leq 5$ ) and implements all of L0 through  $N$ . Levels are strictly cumulative and contiguous. L0 is a mandatory baseline but is NOT a claimable level — the minimum claimable badge is P00<sup>2</sup>L 1.0 Level 1.

| Level                                                               | Adds                                                                                                                                                                                                                            | Errors detectable                           |
|---------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------|
| <b>L0</b> Un-structu-<br>red (ba-<br>seline,<br>not clai-<br>mable) | Plain text. No sec-<br>tions, no params, no<br>anything — nothing<br>is emitted for it, so<br>its own # / ##<br>markdown headings<br>are free (the reser-<br>ved-level rule<br>reaches only a de-<br>clared section).           | —                                           |
| <b>L1</b> Struc-<br>tured                                           | Sections (the<br>@@@section key-<br>word and dotted<br>sub-sections pa-<br>rent.child — NO<br>numbering, NO<br>toggles yet); identi-<br>ty in the source<br>(@@@template +<br>@@@name required,<br>@@@description<br>OPTIONAL). | INVALID_SYNTAX , DUPLI-<br>CATE_DECLARATION |

| Level                                    | Adds                                                                                                                                                                                                                 | Errors detectable                                                                                                                                                                                                                     |
|------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>L2</b> Procedural                     | Includes, parameterized includes, cycle detection.                                                                                                                                                                   | + CIRCULAR_INCLUDE , AMBI-GUOUS_INCLUDE , UNDECLARED_INCLUDE_PARAMETER , UNDEFINED_REFERENCE                                                                                                                                          |
| <b>L3</b> Structured data and validation | Parameters, constants, attachments ( fixed / to-include ), select , declarative constraints, parameter sets, deprecated, aliases.                                                                                    | + the parameter validation set ( TYPE_MISMATCH , CONSTRAINT_VIOLATION , INVALID_CONSTRAINT , SELECT_INVALID_OPTION , SYSTEM_VARIABLE_OVERRIDE , IMMUTABILITY_VIOLATION ), ATTACHMENT_NOT_FOUND , ATTACHMENT_REQUIRED , ALIAS_CONFLICT |
| <b>L4</b> Object-oriented (OO #1)        | Template inheritance (inline inherits clause) + the section-modifier toolbox: @@@section virtual , @@@section final , <b>presence toggles ( ? / ! )</b> , placement clauses, template-axis parent / self references. | + CIRCULAR_INHERITANCE , INVALID_SYNTAX (virtual+final), VIRTUAL_SECTION_HAS_BODY , OVERRIDE_OF_FINAL_SECTION , UNIMPLEMENTED_VIRTUAL_SECTION , OVERRIDE_CONTRACT_VIOLATION , INVALID_SECTION_PLACEMENT , INCLUDE_OF_VIRTUAL_SECTION  |

| Level              | Adds                                                                                                                                                                                                                                                                                                                       | Errors detectable                                                                                                                                                                                                                                                                   |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| L5 OO <sup>2</sup> | All L4 plus <b>collections with inheritance</b> (inherits on the <code>@@@collection</code> header), the <code>virtual</code> / <code>final</code> modifiers on a member's <code>@@@template</code> header, member override, and collection-axis <code>^parent.&lt;template_id&gt;</code> / <code>^self</code> resolution. | + every collection-axis error: <code>CIRCULAR_COLLECTION_INHERITANCE</code> , <code>UNKNOWN_COLLECTION</code> , <code>AMBIGUOUS_COLLECTION</code> , <code>UNIMPLEMENTED_VIRTUAL_TEMPLATE</code> , <code>OVERRIDE_OF_FINAL_TEMPLATE</code> , <code>VIRTUAL_SIGNATURE_MISMATCH</code> |

### 11.1 — Conformance badge

Every conforming implementation **MUST** state both the spec version and its level, in the form `P002L <version> Level <N>` (e.g. `P002L 1.0 Level 4`, ASCII `P002L 1.0 Level 4`). A level without a version is not a valid badge.

### 11.2 — Folders are cross-level

Folders (storage with no `@@@collection` block) **MUST** be supported at every level (L0–L5). They are purely organizational and carry no compositional semantics.

### 11.3 — L0 is mandatory

Every conformant implementation **MUST** accept and render unstructured templates. There is no « lower » level than L0.

## 11.4 — Mixed-level behavior

An implementation conforming below L5 MUST NOT silently give a recognized construct a DEGRADED meaning. Faced with an `inherits` clause on a `@@@collection` header it does not implement, it MUST do one of: reject the input as an unsupported construct, preserve it unrendered and refuse to render that collection, or declare an explicit non-conformant mode. It MUST NOT accept the clause and quietly treat the entity as a plain folder — the same source would then yield two different results across engines.

## 11.5 — Interoperability

Two implementations claiming the same level MUST render the same input prompt to **byte-identical** output (§6.1 Phase 11). Any downstream non-determinism is the AI's, not POO<sup>2</sup>L's.

## Section XII — Decision matrix — what to use when

A flowchart-in-table-form for the most common authoring decisions.

### 12.1 — Section presence

| You want...                                                            | Use                                 |
|------------------------------------------------------------------------|-------------------------------------|
| The section to always appear in the output, no question asked          | <code>@@@section foo</code>         |
| The user to be asked at instantiation, with the section off by default | <code>@@@section? foo : desc</code> |
| Same, but on by default                                                | <code>@@@section! foo : desc</code> |

### 12.2 — Section over inheritance

| You want...                                                     | Use                                                                          |
|-----------------------------------------------------------------|------------------------------------------------------------------------------|
| Children can override the section freely                        | Plain <code>@@@section &lt;name&gt;</code>                                   |
| Children MUST implement the section (you provide only the slot) | <code>@@@section virtual &lt;name&gt;</code><br>(modifier after the keyword) |
| Children MUST NOT override the section (you fix the content)    | <code>@@@section final &lt;name&gt;</code><br>(modifier after the keyword)   |

## 12.3 — Section content reuse

| You want...                                    | Use                                                                |
|------------------------------------------------|--------------------------------------------------------------------|
| Just append after the parent's section content | <code>include parent.&lt;section&gt;</code><br>then add            |
| Replace the parent's section content entirely  | Redeclare <code>section &lt;name&gt;</code> with new body          |
| Pull a specific named ancestor's section       | <code>include pa-<br/>rent.&lt;ancestor&gt;.&lt;section&gt;</code> |
| Pull the most specialized version available    | <code>include self.&lt;section&gt;</code>                          |

## 12.4 — Variable values

| You want...                                      | Use                                                                           |
|--------------------------------------------------|-------------------------------------------------------------------------------|
| Fixed at definition, never appears in the dialog | Constant: <code>@@@const X : text = "value"</code>                            |
| Asked at instantiation                           | Parameter: <code>@@@param x : text, "Label"</code>                            |
| Asked at instantiation but optional              | <code>@@@param? x : text = ""</code> (an optional param MUST carry a default) |
| One of N choices                                 | <code>@@@param x : select("a", "b", "c") = "a"</code>                         |
| Validated against a regex                        | <code>@@@param x : text pattern="..."</code>                                  |

## 12.5 — Files

| You want...                                        | Use                                                                  |
|----------------------------------------------------|----------------------------------------------------------------------|
| Always-attached reference file (style guide, logo) | <code>attachment ... : type fixed file "path"</code>                 |
| File chosen by user at instantiation, required     | <code>attachment ... : type to-include, "desc"</code>                |
| Same but optional                                  | <code>attachment? ... : type to-include, "desc"</code>               |
| Embed binary inline (no external file)             | <code>attachment ... : type fixed blob "data:mime;base64,..."</code> |

## 12.6 — Composition

| You want...                                             | Use                                                                                 |
|---------------------------------------------------------|-------------------------------------------------------------------------------------|
| Reuse a fragment across many templates (DRY)            | Extract into its own prompt, <code>include</code> it                                |
| Specialize a prompt by overriding parts                 | <code>inherits</code> clause on <code>@@@template</code> + <code>override</code>    |
| Group related templates (organizational)                | Folder (storage; no <code>@@@collection</code> block)                               |
| Group related templates AND derive from them as a class | Collection ( <code>@@@collection &lt;name&gt; block</code> )                        |
| A whole class of templates with a mandatory member      | Collection + <code>virtual</code> modifier on the member's <code>@@@template</code> |
| A class member that subclasses must NOT override        | <code>final</code> modifier on the member's <code>@@@template</code>                |

## 12.7 — Lifecycle

| You want...                                                     | Use                                                                                 |
|-----------------------------------------------------------------|-------------------------------------------------------------------------------------|
| Rename a prompt without breaking references                     | Add <code>@@@alias old_id</code>                                                    |
| Mark a prompt for retirement                                    | <code>@@@deprecated "use new_id instead"</code>                                     |
| Hide a comment from the AI but keep it for authors              | <code>@@@-- ... , @@@(-- ... )</code> or <code>@@@comment ... @@@end-comment</code> |
| Include POO <sup>2</sup> L syntax literally (for documentation) | <code>@@@verbatim ... @@@end-verbatim</code>                                        |

## 12.8 — Levels

| Library size / sophistication                          | Target level                                                                               |
|--------------------------------------------------------|--------------------------------------------------------------------------------------------|
| A handful of templates, plain text                     | L0                                                                                         |
| Templates with named sections                          | L1                                                                                         |
| You start duplicating fragments                        | L2 (extract + include)                                                                     |
| You need typed, validated, parameterized templates     | L3 (params, constants, attachments, select, constraints, parameter sets, deprecated/alias) |
| You have prompt families with shared structure         | L4 (inheritance, OO #1)                                                                    |
| You manage families of families (classes of templates) | L5 (collections, OO <sup>2</sup> )                                                         |
